Because the Fourier transform is
additive, this is achieved by simply
subtracting the structure factors: $(|F| - |F_C|) \exp(i\alpha C)$. We can also understand
this map as follows. Part of the true
(complex) difference between F and F_C
will be in the direction of F_C , i.e. in the
direction of the difference structure
factor used in the map.

In this article authors show crystal and liquid phase from two dimensional crystals by calculating structure factor (Fourier transform of 2D points).. I have generated set of points in 2D that represent lattice points of a perfect triangular lattice and a non perfect lattice. (images below)

Afterwards, it represents structure factors and electron density, and shows how the Fourier transform interconverts them. The chapter highlights one-dimensional waves, three-dimensional waves, general features of the Fourier transform, and a short review of the same. It also discusses Fourier mathematics and diffraction.

The amplitudes of the waves are proportional to the atomic scattering factors f_0 and f_1 . The phases differ by the angle ϕ_1 . The resultant vector represents the two-atom structure factor with amplitude F_{hkl} . Note that there is a net phase ϕ arising from the phase difference due to the offset in position between the two sets of diffracting ...

A fast Fourier transform (FFT) is an algorithm that computes the discrete Fourier transform (DFT) of a sequence, or its inverse (IDFT). Fourier analysis converts a signal from its original domain (often time or space) to a representation in the frequency domain

and vice versa. The DFT is obtained by decomposing a sequence of values into components of different frequencies.
